## A G R A D E C I M I E N T O S

Nuestro eterno agradecimiento a nuestros Catedráticos Asesores, por la sugerencia del Tema, por los invaluables consejos y por su dirección en el presente trabajo.

Así mismo nuestra gratitud al Señor Enrique Núñez de La Torre Peña, por su acertada y valiosa ayuda en la parte mecanográfica de la Tesis.

ESPECIFICACIONES DE LA TESIS DE GRADO DE LOS SEÑORES BACHILLERES :  
FRANKLIN AMARU TAIPE GUARDIA Y OSWALDO MAXIMO ALVAREZ DELGADILLO.

Dados los planos arquitectónicos adjuntos :

- 1.- Efectuar la estructuración más corriente
- 2.- Efectuar el análisis sísmico de la estructura por diferentes métodos.
- 3.- Analizar y comparar los resultados obtenidos
- 4.- Indicar conclusiones y efectar recomendaciones.

Lima, 7 de Noviembre de 1,969

---

Ing°. Julio Kuroiwa Horiuchi

## I N T R O D U C C I O N

- El Perú se encuentra situado en una zona sismicamente activa denominada circum pacífico, razón por la que todo tipo de edificación que se proyecte debe realizarse con las seguridades del caso para que al actuar las fuerzas sísmicas no peligre la estabilidad de la estructura y por ende no ocurra la pérdida de la vida de las personas y desde luego pérdidas económicas, lo que a la postre signifique un atraso en el desarrollo del país.
- Cuando en un evento sísmico se produce el colapso de una estructura, son varios los factores que originan que esta falle, tales como la proximidad del epicentro, la magnitud del sismo, las características geológicas de la zona y el tipo de suelo, amplificación dinámica, calidad de los materiales, aptitud de mano de obra, mala estructuración deficiencias en los elementos para sopor tar acciones sísmicas, etc.
- En la actualidad es muy frecuente en nuestro medio el uso de mu ros de concreto armado ( denominado también placas estructurales o paredes sísmicas). Las razones del uso de estos elementos obe decen unas veces a razones de funcionalidad arquitectónica, y otras para asegurar la estabilidad de una estructura que no tie ne suficientes elementos rígidizantes.
- En el presente trabajo se presentan métodos sísmicos que permiten evaluar los cortes y momentos, inducidos por fuerzas sísmicas, en los elementos resistentes de una estructura constituida por pla cas y pórticos.
- Con el deseo de analizar un edificio ya proyectado reunimos un buen número de proyectos que nos fueron proporcionados por los

arquitectos. Pero, ¡Oh sorpresa! todos los proyectos constituyen una belleza que no admite discusión, pero al analizar la geometría de los mismos, nos encontramos que un gran porcentaje de ellos estaban mal estructurados, había por ejemplo edificios que presentaban en un extremo una placa y paralelamente a ella pórticos, otros edificios presentaban plantas en forma de T, L, I, U, H, etc., edificios sin disposición simétrica de masas y rigideces que traen como consecuencia problemas de torsión etc. A lo anterior habría que agregar que al tratar de ubicarlos en ejes, era imposible hacerlo, por la posición arbitraria de columnas y placas.

- Ante estas circunstancias, por nuestras apreciaciones, decidimos elaborar el bosquejo de un edificio hipotético, que si bien no se iba a construir, en cambio lo podríamos tomar como objeto problema para análisis del mismo por cargas horizontales. El edificio bosquejado es similar a un gran número de edificios que se proyectan en Lima, placas en los extremos y caja del ascensor en el núcleo central del edificio, procurando de esta manera, satisfacer en lo posible la belleza arquitectónica y la estructuración del mismo.
- Se han desarrollado los métodos presentados por :

KIYOSHI MUTO              En la Conferencia Mundial de Ingeniería Antisísmica. (Julio de 1956 en la Universidad de California).

PHILLIP L. GOULD, cuyo método lo desarrolla con la teoría de "Diferencias finitas" y lo presentó para subgraduación en la Northwestern University, Evanston III y aparece publicado en el Journal del ACI en Enero de 1965 en las páginas 45-68.

YACK LOPEZ ACUÑA, Con el Método Matricial, Octubre 1969.

FAZLUR R. KHAN Y JOHN A. SBAROUNIS, Trabajo presentado al American Society of Civil Engineers, Journal of the Structural Division - Junio 1969. Páginas 285 - 355.

- El Método de Muto es el más difundido en el medio, sus cálculos han sido desarrollados con máquinas de operaciones aritméticas. Su desarrollo es sencillo y obedece a proceso iterativos. Los otros métodos exigen un cálculo más laborioso por lo que se ha recurrido al auxilio de la computadora de la Universidad.
- Se incluyen también los digramas de los programas utilizados y gráficos que relacionan la deformada de la estructura, obtenida mediante los métodos analizados.

## CARACTERISTICAS DE LA ESTRUCTURA ESTUDIADA Y DE LAS SOLICITACIONES

### CARACTERISTICA DE LA ESTRUCTURA

En el presente trabajo, la estructura objeto del análisis sísmico consta de 10 pisos y su planta es de forma rectangular. Los pisos tienen una altura típica de 2.90 m. de altura con excepción del primero que tiene 3.30 m de altura.

Los pisos están constituidos por una losa aligerada con armadura principal en un solo sentido, y sus apoyos son vigas principales que están ubicadas en pórticos de mayor número de crujías, denominándose vigas secundarias, las perpendiculares a dichas vigas.

La disposición de placas y columnas se han dispuesto de modo que la participación de rigideces sea de mayor contribución. En una dirección las placas, y en otra las columnas. Así, en la dirección O - E se orientó la mayor dimensión de las columnas (sentido más largo del edificio) y en la dirección N - S se orientaron las placas de concreto ( Placas laterales y cajón del ascensor).

En ambas direcciones se presentan dos casos de estudio:

El primero; considerando un ancho colaborante del ala, y el segundo; tomando la caja del ascensor como conjunto.

En la dirección N - S se considera primero que la longitud de las placas laterales sea una porción del ancho del edificio, y segundo que la longitud de dichas placas sea todo el ancho.

Las dimensiones de las columnas se han variado de la siguiente manera: de abajo hacia arriba; del nivel cero al cuarto piso; del cuarto al séptimo piso y del séptimo piso al décimo piso.

Las dimensiones de los elementos se muestran en planta y elevación en las figuras respectivas.

## ESTRUCTURACION

Por las razones de la forma geométrica alargada de la planta del edificio (rectangular), es conveniente disponer las placas en el sentido más corto del edificio, y en el otro sentido orientar las columnas de modo que ofrezcan una mayor rigidez.

Para determinar si es necesario la utilidad de las placas, se partió de considerar soportado el edificio únicamente por marcos, los cuales quedan definidos en las luces de sus crujias y separación de los pórticos por simple inspección de los ambientes en la distribución arquitectónica del mismo.

El uso de placas resultará de comparar la deflexión relativas de los entrepisos de la estructura, con la máxima permitida.

Para el cálculo de las deflexiones se aplicó las fórmulas de las constantes de rigidez de entrepiso de Wilbur.

La deflexión máxima permitida se calculó con la fórmula proporcionada en el reglamento peruano de diseño sísmico.

De la comparación de los desplazamientos relativos de los entrepisos que dependen principalmente de la flexibilidad de las columnas del entrepiso considerado y de las vigas de los pisos adyacentes, se dispuso la colocación de las placas en el ascensor y en los extremos del edificio, en su lado mas corto. En el sentido transversal al lado corto, figuran las columnas en su mayor dimensión, lo mismo que la placa del ascensor.

PROYECTO DE GRADO: EDIFICIO DE 10 PISOS

OSWALDO ALVAREZ Q. & FRANKLIN TAPE G.

PROYECTO DE GRADO EDIFICIO DE 10 PISOS

OSWALDO ALVAREZ & FRANKLIN TAPIA G  
PROHOCION 1960

PLANTA TIPICA

ESC 1:50

SOLICITACIONES:

Cargas de Gravedad: En el cálculo de las cargas permanentes de servicio se consideró lo siguiente:

En la Azotea ..... Cubierta de ladrillo pastelero mas enlucido de yeso en cielo raso..... 100 Kg/m<sup>2</sup>  
 Aligerado ( h=25 cms ) ..... 350 Kg/m<sup>2</sup>  
 Carga perimetral lineal (parapeto) ..... 400 Kg/m

En los pisos Típicos:

Cubierta de piso terminado y enlucido de yeso en cielo raso . 100 Kg/m<sup>2</sup>  
 Aligerado ( h=25cms ) ..... 350 Kg/m<sup>2</sup>  
 Tabiques de ladrillo ..... 100 Kg/m<sup>2</sup>

En cuanto a la S/C de servicio se consideró :

En la azotea ..... 150 Kg/m<sup>2</sup>  
 En los pisos típicos..... 250 Kg/m<sup>2</sup>

Determinación del peso del edificio:

Peso de Aligerados:

$$\begin{aligned} \text{Area neta} &= \text{Area total} - \text{Area (escalera + Ascensor)} \\ &= 12.60 \times 25.40 - (3.8 \times 3.4 + 3.8 \times 2.15) \\ &= 319.9 - 21.1 \end{aligned}$$

$$\text{Area neta} = 298.8 \text{ m}^2 \quad 299 \text{ m}^2$$

En Azotea ó Planta Típica : Aligerado de 25 cms ..... .350 Tn/m<sup>2</sup>

Piso acabado y cielo raso.. .100 Tn/m<sup>2</sup>  
 Total = .450 Tn/m<sup>2</sup>

$$\text{Peso} = 299 \text{ m}^2 \times .450 \text{ Ton/m}^2 = 134.5 \text{ Ton.}$$

Peso Unitario de las Vigas:Peso de Vigas:

| 1  | 134.50      | 45.11      | 40.55       | 23.73       | 4.56        | 7.80        | 256.25  | 1  |

$$\sum = 2,460.285$$

Como :

$$P = CM + 25\%CV \dots\dots\dots (I)$$

tambien:

$$CM = 2,460.285 \text{ Ton} \dots\dots\dots (1)$$

$$CV = 0.150 \text{ Ton/m}^2 \times 299\text{m}^2 + 0.250 \times 9 \times 299$$

$$\text{Luego } 0.25CV = 179.40 \text{ Ton} \dots\dots\dots (2)$$

reemplazando (1) y (2) en (I)

$$P = 2,460.285 + 179.40 = 2,639.685 \text{ Ton}$$

---

ACCION DEL SISMO:

Se siguió las normas peruanas de diseño antisísmico.

La fuerza cortante total "H" en la base del edificio se determinó con la fórmula:

$$H = U K C P$$

Donde :  $U =$  Coeficiente que depende del uso de la edificación y el índice sísmico = 0.8

$K =$  Coeficiente que depende del tipo de estructuración es - cogida para el edificio = 1.0

$C = 0.05 / \sqrt[3]{T}$ ; coeficiente sísmico que determina el porcentaje de peso que debe tomarse como cortante en la base.

Luego de realizar varios cálculos previos se halló ;

$$H_x = 0.048 P = 126 \text{ Ton}$$

$$H_y = 0.054 P = 142 \text{ Ton}$$

La fuerza cortante total en la base se distribuyó en lo alto del edificio , de acuerdo con la siguiente fórmula:

$$F_i = 0.95 H \frac{w_i h_i}{\sum w_i h_i}$$

El 5% restante se consideró concentrado en el nivel de la azotea.

Se consideró además que en la azotea estuvo concentrada el 20% de los elementos situados encima de su plano ( el peso de casetas de máquina de ascensor, tanque de agua ; se asumió 21 Ton )

Finalmente se encontró los siguientes cortantes:

| N  | V <sub>x</sub> | V <sub>y</sub> |
|----|----------------|----------------|
| 10 | 46.24          | 49.43          |
| 9  | 65.75          | 71.41          |
| 8  | 83.22          | 91.10          |
| 7  | 98.76          | 108.50         |
| 6  | 112.28         | 123.74         |
| 5  | 123.65         | 136.55         |
| 4  | 132.74         | 146.80         |
| 3  | 139.68         | 154.62         |
| 2  | 144.32         | 159.88         |
| 1  | 146.68         | 162.71         |

Unidades : Toneladas.

$K_i$  = Rigidez de Traslación (Tn/m) : Método Matricial.

$$\varepsilon = \text{Error Relativo} = \frac{\Delta_o - \Delta_i}{\Delta_o} \leq \pm 0.1$$

$$= \frac{\phi_o - \phi_i}{\phi_o} \leq \pm 0.1$$

## M E T O D O   D E   M U T O

E X P O S I C I O N   G E N E R A L

Es un método iterativo que permite calcular la fuerza cortante en los elementos resistentes, distribuyendo proporcionalmente el corte de un piso a los valores "D" que son constantes para un elemento. También permite encontrar los puntos de inflexión.

El valor "D" en un nivel determinado es la fuerza de corte necesaria para producir en un elemento un desplazamiento relativo unitario. Para muros en voladizo se asume una distribución de corte y se calculan las deformaciones, pudiéndose de esta manera calcular D. Se calcula luego los cortes y se comparan con los iniciales, el proceso iterativo cesará cuando dichos valores sean parecidos. Para la interacción entre muros y pórticos se supone que las columnas adyacentes sufren una deformación continua con el muro, y que las vigas que llegan al muro, tienen en el extremo de contacto con este una pendiente cuyo valor es el mismo que el de rotación del muro. Por distribución de momentos se calculan los momentos en las columnas adyacentes y en las vigas antes mencionadas; luego se calcula los valores de esas columnas y se obtendrán momentos de corrección debido a las vigas.

A los momentos de la placa en voladizo se le superpone los de corrección y se calculan las deformaciones y valores D. Se compara el inicial como volado con el calculado, si no son similares se hace una nueva interacción partiendo con los cortes del ciclo anterior. Se continúa con el proceso iterativo hasta conseguir que los valores D iniciales y D finales sean parecidos.

Obtenidos los valores D se calcula la torsión si es que existe excentridad entre el centro de corte (Centro de masas G) y el centro de rigidez (Centro de valores D).

DEFORMACION POR CORTE

$$\text{La deformación por corte es } \delta_{sn} = \frac{R V_n h_n}{6 A_{wn}} \beta$$

R = Coeficiente de corte ( 1.0 a' 1.2 )

V<sub>n</sub> = Fuerza cortante en el piso n

h<sub>n</sub> = Altura del piso n

G = Módulo elástico al corte

A<sub>wn</sub> = Área de la sección en el piso n

β = Coeficiente de deformación plástica ( 1 a 10 )

$$\text{Usando la unidad común } \left( \frac{h_n^2}{12 E K_0} \right)$$

$$\text{Llamando } \frac{R V_n}{A_{wn}} = \Delta_{sn} \quad \frac{E}{G} = 2.3$$

$$\delta_{sn} = \Delta_{sn} \times \frac{27.6 K_0}{h_n}$$

DEFORMACION POR FLEXION

$$\delta_1 = h_n \theta = h_n \sum_{l=1}^{n-1} \left( \frac{M_l h_l}{E I_c} \right) \quad (\text{Área del diagrama de momentos})$$

$$\delta_2 = \frac{1}{2} \frac{M_n}{E I_n} h_n^2 \quad (\text{Momento del diagrama de momentos}).$$

Considerando la unidad común  $\frac{h_n^2}{12E K_0}$  y llamando

$$K_{wn} = \frac{I_n}{h_n} \cdot \frac{1}{K_0} \quad \dots \dots \dots$$

$$\delta_{Bn} = 4\Delta_{Bn} \left( -\frac{3}{h_n} \right) ; \text{ donde} \\ \Delta_{Bn} = \left( \sum_{i=1}^{m-1} \frac{M_i}{K_{wi}} \right) + \frac{1}{2} \frac{M_m}{K_{wm}}$$

### ROTACION DE LA FUNDACION

La deflexión de un piso cualquiera está dada por :

$$\delta_{Rn} = \theta h_n$$

### DEFLEXION TOTAL

$$\delta_{wn} = \delta_{sn} + \delta_{Bn} + \delta_{Rn}$$

### INTERACCION ENTRE MUROS Y MARCOS

- 1º) Se asume una configuración de corte y se calcula la deflexión del muro como si estuviese en voladizo.

2º) Asumiendo que los números contiguos mantienen una deformación continua con el muro, se calculan las deformaciones :

$$\text{ROTACION TOTAL DE LA COLUMNA : } R_n = \frac{V_n}{D_{wn}} \cdot \frac{h_n}{2} \dots \text{UNIDAD } \frac{1}{6EKO}$$

$$\text{ROTACION DEBIDA A LA DEFORMACION POR CORTE : } R_{sn} = \delta_{sn} \cdot \frac{h_n}{2} \text{ UNIDAD } \frac{1}{6EKO}$$

ROTACION DE LA PARED DEBIDA A FLEXION Y ROTACION DE LA.

FUNDICION :  $R_{BR_n}$

$$R_{BR_n} = R_n - R_{sn}$$

$$\text{ULTIMO PISO } \theta_u = R_{BR_{m-1}}$$

$$\text{PISO INTERMEDIO } \theta_n = \frac{R_{BR_n} + R_{BR_{n-1}}}{2}$$

$$\text{ROTACION DE LA VIGA : } R_{Bn} = - \frac{\theta_n}{2} - \frac{L_1}{L_2}$$

3º) CALCULO DE MOMENTOS EN EXTREMOS

$$\text{SLOPE DEFLECTION } M_{AB} = 2EK(2\theta_A + \theta_B - 3 \frac{\delta}{L})$$

$$M_{BA} = 2EK(2\theta_B + \theta_A - \frac{3\delta}{L})$$

(19)

### MOMENTOS EN LAS VIGAS.

Escogiendo unidad común ( $1 \div 6EK_o$ )

$$M_{AB} = \frac{2EK}{6EK_o} (2\theta_A - 3R_B) = \frac{K_B}{3} (2\theta_A - 3R_B)$$

$$M_{BA} = \frac{2EK}{6EK_o} (\theta_A - 3R_B) = \frac{K_B}{3} (\theta_A - 3R_B)$$

### MOMENTOS EN COLUMNAS.

$$M_{AB} = M_{BA} = 2EK (-3R_n)$$

$$\text{UNIDAD COMUN } 6EK_o \quad \text{y} \quad K/K_o = k_c$$

$$M_{AB} = M_{BA} = -k_c R$$

4º Se distribuyen los momentos. (Se realiza un ciclo por ser todo aproximado).

5º Se calcula valor "D" en columnas adyacentes.

$$V = (M_B + M_T)/h$$

$$\delta = h R_n$$

$$V/\delta = (M_B + M_T)/h^2 R_n \quad ; \quad V/\delta = D \quad \text{Si está expresado en unidad } \frac{h^2}{12EK_o}$$

$$D = (M_B + M_T)/2R_n h_m^2 \times 2 \times 6EK_o$$

$$D_m = (M_B + M_T)/2R_n \quad \text{UNIDAD COMUN } (1 \div 6EK_o)$$

6º) Se determinan los momentos en columnas y vigas

COLUMNAS :

$$M_T' = V \cdot Z_T = \frac{V \cdot h}{M_T + M_B} \times M_T \quad (\text{SUPERIOR})$$

$$M_B' = V \cdot Z_B = \frac{V \cdot h}{M_T + M_B} \times M_B \quad (\text{INFERIOR})$$

SIENDO :

$$V = D \frac{(\Sigma V)}{(\Sigma D)}$$

VIGAS

Estos momentos se obtienen equilibrando los debidos a las columnas, distribuyendo proporcionalmente a los valores de los momentos de vigas encontradas en la distribución de momentos.

7º) Se determinan los momentos de corrección en el eje del muro.

8º) Se superpone los momentos en volado y de corrección, y se calcula la deformación por flexión, a la que se añade la inicial por corte y rotación y se determina el valor D.

9º) Se compara D inicial y final, si la diferencia es muy grande, se repite el procedimiento.

EFFECTO DE INTERACCION :

PLACA 2

$$\text{Como : } R_n' = R_{BRn}' + R_{Sn}'$$

$$\text{También : } R_{Sn}' = \sigma_{Sn} h / 2 \quad \left. \right\} \quad \frac{1}{6EK_0}$$

$$R_n' = \frac{V_w}{D_w} \cdot h / 2$$

$$\text{Luego : } \theta_n = \frac{R_{BRn}' + R_{Sn}' - 1}{2}$$

$$R_v' = -\frac{\theta_n}{2} \cdot \frac{L_1}{L_2} \Rightarrow \frac{L_1}{2L_2} = \frac{370}{2 \times 535} = 0.3457$$

NOTA : Unidades de  $V_x \rightarrow T_n$

M E T O D O D E M U T O

Luego de la Distribución : Graficamos los valores y hallamos el valor  $D_f$  de la columna adyacente a la placa :

$$D = \frac{M_B + M_T}{2R}$$

M E T O D O      D E M U T O

Calculado el valor "D", de la columna adyacente realizamos la distribución del cortante :

| Nº | $\Sigma D_{Por}$ | D <sub>P2</sub> | $\Sigma D_T$ | V <sub>T</sub> | $\frac{V_T}{\Sigma D_T}$ | V <sub>Por</sub> | V <sub>P2</sub> | V <sub>CE2</sub> | Nº |

NOTA : LAS UNIDADES SON (Tn-m)

M E T O D O · D E M U T O

- Como se podrá ver en el cuadro v; las columnas  $\alpha$  y  $\beta$ ; no se parecen; por lo tanto.
- Se tiene que realizar tres iteraciones más, hasta que se consiguió que :

$$D_{f^i} \approx D_{f^{i-1}} \quad \text{o sea} \quad + D_{f^4} \approx D_{f^3}$$

- Los pasos a seguir son los mismos
- Se presenta la cuarta iteración, y también el cuadro general, para ver su variación a la convergencia.

DISTRIBUCION DE CORTE : Para la Cuarta Iteración.

Corrección por Torsión: Como se podrá ver en la distribución de elementos resistentes es totalmente simétrica y la caja del ascensor está colocada en el centro de rigideces. La correcc. por tors. es mín.

 MOMENTO DE VOLADO + MOMENTO DE CORRECCION = MOMENTO FINAL DEL MURO  
 PRIMERA ITERACION : ( CASO II )

UNIDADES : M ( Tn - m )

ESCALA ; 1 / 50 .

M E T O D O M U T 0

Como se podrá ver; al comparar  $D_i \Rightarrow Df_1$ ; donde  $D_i$  (considerando como volado); son diferentes.

- Se tendrá que realizar otra iteración y comparar  $Df_2 \Rightarrow Df_1$ ; y así sucesivamente.
- En este caso se llegó hasta:  $Df_4 = Df_3$ .
- Los pasos a seguir son los mismos.

DISTRIBUCION DE CORTE: Para la 5ta. Iteración : ( $Df_4 \neq Df_3$ )

## C A S O I I : M U T O

## ANALISIS DE ESFUERZOS DEL PORTICO 1 y 3

Corrección por torsión: Como se verá en el gráfico N°

La distribución de los elementos resistentes es simétrica, el efecto de torsión es mínima; lo que no afecta los primeros valores.

METODO DE MUTORESUMEN:ANALISIS SISMICO: ( O - E )

En el presente método se ha analizado los siguientes casos:

a) Considerando la placa aislada:  $I = 1.5163 \text{ m}^4$

- En la cual el método no llegó a converger; debido a la flexibilidad de ésta; después de realizar varias iteraciones, al resolver la interacción; VIGA-PLACA.

b) Considerando un ancho colaborante:  $I = 1.9617 \text{ m}^4$

- Se tomo como ancho colaborante ( $\frac{1}{3}b$ ) que equivale en un 30% del momento de inercia del caso anterior. Al resolver la interacción VIGA-PLACA; se necesitó hacer una variación en el método; para obtener un valor de " $Df_1$ "; la cual nos sirvió de base para proseguir con el método y realizar tres iteraciones más; hasta que se consiguió encontrar:  $Df_3 \approx Df_4$

C A S O : I

La variación, consistió en tomar el 50% del momento de Corrección, ya que al finalizar la PRIMERA ITERACION DE LA INTERACION nos encontramos que:  $2 \cdot 4\Delta_{Mc} > 4\Delta_{Mv}$

Lo que originaba, que se iban a encontrar deflexiones negativas y por lo tanto; rigideces de la placa también negativa ( $D_p$ ) porque :

$$D_p = \frac{V_p}{-(\delta_{Bm} + \delta_{Sm})}$$

$$D_p = \frac{V_p}{-\delta_{Wm}} = (-)$$

y no se podía seguir con las iteraciones, ya que esto traía como consecuencia cortantes negativas.

- Al tomar el 50%  $M_c$ ; se hallaba un valor :  $2 \cdot 4\Delta_{Mv} - 4\Delta_{Mc} =$  positivo; lo que traería como consecuencia un valor de " $\delta_w$ ", positivo y un valor  $+D_{f_1}$ , (Rigidez de la placa; al finalizar la primera iteración) POSITIVO que nos iba a servir para hallar una nueva distribución de CORTANTE para la placa; y así proseguir de nuevo con el método.

¿Cómo justifica usted; el porcentaje tomado?

- 1.- El método de muto es iterativo:
- 2.- Se empieza el método asumiéndonos en una distribución de Cortante.
- 3.- Estos nuevos valores de Corte; calculados con los valores " $D_{f_1}$ " pueden considerarse como los asumidos y empezar la iteración como volado y posteriormente con la interación; y se verá que con estos nuevos cortantes el método converge.
- 4.- La deformada de la estructura deberá seguir la dirección de la deformada libre; principalmente en los pisos inferiores.

SENTIDO N-S (2do. Caso)CALCULO DEL D DE COLUMNAS

Para esta situación, la estructura tiene en ambos extremos placas en toda su extensión, hay dos pórticos B y E que son iguales, y el ascensor se halla entre los pórticos C y D que también son iguales. Considerando los resultados obtenidos en el 1er.caso se tendrá:

PORTEICO B

| n    | $\Sigma D$ |
|------|------------|
| 10-8 | 5.25       |
| 7-5  | 8.76       |
| 4-2  | 9.71       |
| 1    | 17.27      |

PORTEICO C

| n  | D-C1 | D-C2 | D-C3  |
|----|------|------|-------|
| 10 | 1.64 | 6.90 | 1.065 |
| 9  | 1.52 | 5.00 | 1.065 |
| 8  | 1.43 | 5.20 | 1.065 |
| 7  | 1.80 | 5.35 | 1.02  |
| 6  | 1.77 | 5.25 | 1.02  |
| 5  | 1.65 | 5.35 | 1.02  |
| 4  | 2.62 | 5.72 | 1.42  |
| 3  | 2.50 | 5.75 | 1.42  |
| 2  | 2.45 | 5.90 | 1.42  |
| 1  | 2.25 | 5.80 | 1.74  |

## M E T O D O      D E      M U T O

RESUMENCASO I : Placas de ascensor y laterales con columnas a cada lado.

No puede continuarse el proceso iterativo.

En las tres primeras iteraciones el método no es convergente.

En la cuarta iteración, para la placa del ascensor, los valores que corrigen a la placa como voladizo, son tan grandes en magnitud que a partir del quinto Nivel sobrepasan a los de ésta.

El diagrama de momentos cambia de signos de la siguiente manera:

a) Para la placa del ascensor :

En la segunda iteración entre el tercer y cuarto nivel.

En la tercera iteración entre el séptimo y octavo nivel.

En la cuarta iteración entre el primer y segundo nivel.

b) Para la placa lateral :

En la segunda iteración entre el cuarto y quinto nivel

En la tercera iteración entre el sexto y séptimo nivel

En la cuarta iteración entre el tercer y cuarto nivel.

Por ser las placas flexibles, no se puede seguir corrigiendo el  $\Delta M$ , en la primera iteración la corrección se hizo de modo que el desplazamiento por flexión fuera similar en las placas, ya que el desplazamiento por corte afecta muy poco y solo en los pisos bajos. En la segunda iteración el  $\Delta M$  siguió siendo grande y se consideró un 90%.

CASO II Placas de ascensor con columnas a uno y otro lado. Placas laterales sin iteración.

En este caso nos encontramos que las placas laterales tienen gran rigidez y la del ascensor es flexible.

Para la placa lateral, consideramos únicamente voladizo, y tuvo una convergencia rápida en la tercera iteración se encontró su valor D.

La placa del ascensor si presenta interacción, el D como volado se obtuvo en la octava interacción.

Después de la tercera interacción tenemos :

| N  | Lateral  |      | Asc. volado |       | Asc. I   |    | Asc. II  |    | Asc. III |      |
|----|----------|------|-------------|-------|----------|----|----------|----|----------|------|
|    | $\delta$ | D    | $\delta$    | D     | $\delta$ | D  | $\delta$ | D  | $\delta$ | D    |
| 10 | .196     | 106  | .202        | 2.07  | .012     | 52 | .49      | 11 | .0002    | 1000 |
| 9  | .198     | 158  | .202        | 4.26  | .015     | 54 | .46      | 20 | .0050    | 730  |
| 8  | .197     | 205  | .199        | 6.20  | .021     | 57 | .46      | 22 | .0232    | 180  |
| 7  | .192     | 250  | .194        | 7.83  | .028     | 53 | .43      | 23 | .0322    | 130  |
| 6  | .183     | 300  | .184        | 10.00 | .036     | 50 | .38      | 22 | .0322    | 124  |
| 5  | .168     | 362  | .171        | 13.65 | .042     | 54 | .34      | 25 | .0339    | 124  |
| 4  | .149     | 442  | .153        | 17.20 | .047     | 54 | .29      | 29 | .0334    | 130  |
| 3  | .123     | 570  | .127        | 25.50 | .047     | 66 | .23      | 34 | .0336    | 136  |
| 2  | .091     | 790  | .091        | 46.10 | .044     | 97 | .15      | 58 | .0246    | 215  |
| 1  | .044     | 1635 | 0.10        | 4.55  | .027     | 70 | .05      | 69 | .0091    | 350  |

Después de analizar que cuadro, se llegará a establecer que no se puede continuar el proceso iterativo por las siguientes razones :

- El proceso no es convergente
- Observando además el cuadro de cálculo del D en la tercera iteración, se nota que los valores  $4\Delta M(\pm)$  son casi parecidos, por lo que su diferencia es muy pequeña y por lo tanto los valores de desplazamiento de la placa es pequeño, lo que significaría una rigidez grande para la placa del ascensor, lo que no puede ser ya que si bien es cierto que el D de la placa del ascensor tiene que variar su valor final debe paracersele, y a demás como los valores D para las placas laterales son mucho mayores que los del ascensor, la deformada final no variará fundamentalmente con la deformada inicial.
